

1. Answer:

- a) Creating the 4th process and grant its initial request would result in a safe state:

Process	Claim	Allocation	C-A	Available
1	70	45	25	25
2	60	40	20	
3	60	15	45	
4	60	25	35	

There is sufficient free memory (25 units) to guarantee the termination of either P1 or P2. After that, the remaining three processes can be completed in any order.

- b) Creating the 4th process and grant its initial request would result in an unsafe state:

Process	Claim	Allocation	C-A	Available
1	70	45	25	15
2	60	40	20	
3	60	15	45	
4	60	35	25	

There is NO sufficient free memory (15 units) to satisfy any process.

2. Answers:

1. No row in the allocation matrix is all zero, thus no process is marked
2. $W = (2 \ 1 \ 0 \ 0)$, i.e., the available vector
3. Mark P3; $W = (2 \ 1 \ 0 \ 0) + (0 \ 1 \ 2 \ 0) = (2 \ 2 \ 2 \ 0)$
4. Mark P2; $W = (2 \ 2 \ 2 \ 0) + (2 \ 0 \ 0 \ 1) = (4 \ 2 \ 2 \ 1)$
5. Mark P1; no deadlock detected

3. Answers:

- Assume that the table is in deadlock, i.e., there is a nonempty set D of philosophers such that each P_i in D holds one fork and waits for a fork held by neighbor.
- Without loss of generality, assume that $P_j \in D$ is a lefty. Since P_j clutches his left fork and cannot have his right fork, his right neighbor P_k never completes his dinner and is also a lefty. Therefore, $P_k \in D$.
- Continuing the argument rightward around the table shows that all philosophers in D are lefties. This contradicts the existence of at least one righty. Therefore deadlock is not possible.

Self-test

1. A
2. D
3. B
4. D
5. A
6. C
