GE2262 Business Statistics

Topic 7 Inference for the Proportion

Reference

Levine, D.M., Krehbiel, T.C. and Berenson, M.L., *Business Statistics: A First Course*, Pearson Education Ltd, Chapter 7 & 8 & 9

Outline

- Sampling Distribution of the Sample Proportion
- Confidence Interval Estimate for the Proportion
- Sample Size Determination for the Proportion
- Hypothesis Testing for the Proportion

Will Britain Leave EU?

- Express (UK), 22 June 2016: Analysts at TNS surveyed 2,320 adults across the UK online between June 16-22. The baseline results reveal a 2% lead for the EU leave campaign, with support for Brexit at 43% compared to 41% for Remain
- We do not know the true population of British intending to leave EU until the result of the referendum is announced. A common way to gain insights on election or a referendum campaign is to held a survey and based inference on the proportion of success in a sample taken from the relevant population
- In practice, most of these surveys are inaccurate because
 - The involved sample is biased. It does not truly represent the population
 - Some voters had not honestly revealed their voting intention, or they changed their mind after the survey

Sample Proportion

- Let Y be the number of observations belong to the one of the two levels (e.g. success and failure, yes and no, etc.) of a categorical variable in a random sample of n observations
- The proportion of observations belong to one of the two levels (e.g. success, yes, etc.) in the sample

$$p = \frac{Y}{n}$$

is called the sample proportion

Sample Proportion

Cont'd

We saw in Topic 3 that Y, obeys a binomial distribution with

$$P(Y = y) = \frac{n!}{y! (n - y)!} \pi^{y} (1 - \pi)^{n - y}$$

where

P(Y = y) = probability that Y = y events of interest, where y = 0, 1, 2, ..., n

 π = probability of an event of interest, or the population proportion of observations belong to the level of interest

- A small enterprise has 4 staff, N=4 (3 males and 1 female)
- Variable of interest: Gender
- Let Y = no. of male staff, $\pi = \text{proportion of male staff} = 0.75$
- Random samples of size 2 with replacement are taken (n=2)
- As Y obeys a binomial distribution
 - $Price Y \sim B(2, 0.75)$

$$\mu = n\pi = 2 \times 0.75 = 1.5$$

$$\sigma = \sqrt{n\pi(1-\pi)}$$

$$= \sqrt{2 \times 0.75 \times 0.25} = \sqrt{0.375}$$

Cont'd

Sample proportion of male staff, $p = \frac{Y}{n}$ 16 possible sample proportions

Respondent	A (M)	B (M)	C (F)	D (M)
A (M)	2/2 = 1	2/2 = 1	1/2 = 0.5	2/2 = 1
B (M)	2/2 = 1	2/2 = 1	1/2 = 0.5	2/2 = 1
C (F)	1/2 = 0.5	1/2 = 0.5	0/2 = 0	1/2 = 0.5
D (M)	2/2 = 1	2/2 = 1	1/2 = 0.5	2/2 = 1

Probability distribution of p

p	0	0.5	1
P(p)	1/16	6/16	9/16

Cont'd

Summary measures for the sampling distribution of sample proportion

$$\mu_{p} = \sum p_{i} P(p_{i})$$

$$= 0 \left(\frac{1}{16}\right) + 0.5 \left(\frac{6}{16}\right) + 1 \left(\frac{9}{16}\right) = 0.75 = \pi$$

$$\sigma_{p} = \sqrt{\sum (p_{i} - \mu_{p})^{2} P(p_{i})}$$

$$= \sqrt{(0 - 0.75)^{2} \left(\frac{1}{16}\right) + (0.5 - 0.75)^{2} \left(\frac{6}{16}\right) + (1 - 0.75)^{2} \left(\frac{9}{16}\right)}$$

$$= 0.3062$$

$$= \sqrt{\frac{\pi(1-\pi)}{n}} = \frac{\sqrt{n\pi(1-\pi)}}{n}$$

• We say the sample proportion p is an unbiased estimator of the population proportion π

Cont'd

The exact form of the sampling distribution of p is rather complicated. Instead of using the exact distribution of p, it is common to approximate the sampling distribution by a normal distribution

Cont'd

- Suppose you want to estimate the proportion (π) of CityU students who skipped 2 or more classes per week in last semester
- A sample of size n is collected
- You register your data points as categorical observations: Yes, skipped 2 or more classes; or No, skipped 1 or less class
- For subsequent data manipulation, you may code those who skipped 2 or more classes as a 1, and those who skipped 1 or less class as a 0
- Using the numeric coded values, and denotes X_i as the numeric coded value of the ith observed student in the sample, we see that $Y = \sum X_i$ = observed number of students who skipped 2 or more classes $p = \frac{Y}{n} = \frac{\sum X_i}{n}$ = sample proportion of students who skipped 2 or more classes
 - \square is like the formula for the sample mean, so, a sample proportion is a special case of a sample mean 10

Cont'd

■ Since the sampling distribution of p (= $\frac{Y}{n}$ = $\frac{\sum X_i}{n}$) has mean π and standard deviation $\sqrt{\frac{\pi(1-\pi)}{n}}$, then by Central Limit Theorem, sampling distribution of p follows a normal distribution approximately with mean π and standard deviation $\sqrt{\frac{\pi(1-\pi)}{n}}$ for large n

Cont'd

 Hence, for large sample size, the distribution of the random variable

$$Z = \frac{p - \pi}{\sqrt{\frac{\pi(1 - \pi)}{n}}}$$

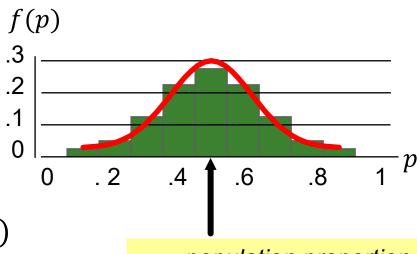

is approximately standard normal

- This statistic can be used to obtain confidence intervals, and hypothesis testing for the population proportion
- In practice, "n is large enough" often means that $n\pi \geq 5$ and $n(1-\pi) \geq 5$, that is π cannot be too small or too large

Cont'd

- Normal approximation can be used if
 - $n \ge 30$
 - $n\pi \geq 5$
 - n(1 π) ≥ 5
 - \rightarrow Sampling distribution of sample proportion $p \sim N(\mu_p, \sigma_p^2)$
- 2 parameters in sampling distribution of sample proportion
 - lacksquare Mean, $\mu_p=\pi$
 - \Box Variance, ${\sigma_p}^2 = \frac{\pi(1-\pi)}{n}$

 π = population proportion

Converting the sample proportion p to Z value

$$Z = \frac{p - \mu_p}{\sigma_p} = \frac{p - \pi}{\sqrt{\frac{\pi(1 - \pi)}{n}}}$$

Sampling Distribution of p

Standardized Normal Distribution

- Suppose that the manager of the local bank determines that 40% of all depositors have multiple accounts at the bank
- If you select a random sample of 200 depositors, what is the probability that the sample proportion of depositors with multiple accounts is less than 0.3?

- Given $\pi =$ population proportion of depositors with multiple accounts = 0.4
- As n=200>30, $n\pi=80>5$, $n(1-\pi)=120>5$ → The sampling distribution of p follows Normal distribution approximately, i.e. $p\sim N(\mu_p,\sigma_p^2)$

$$P(p < 0.3)$$

$$= P(Z < \frac{0.3 - 0.4}{\sqrt{\frac{0.4(1 - 0.4)}{200}}})$$

Cont'd

- Given $\pi =$ population proportion of depositors with multiple accounts = 0.4
- As n = 200 > 30, $n\pi = 80 > 5$, $n(1 \pi) = 120 > 5$ → The sampling distribution of p follows Normal distribution approximately, i.e. $p \sim N(\mu_p, \sigma_p^2)$

$$P(p < 0.3)$$
= $P(Z < \frac{0.3 - 0.4}{\sqrt{\frac{0.4(1 - 0.4)}{200}}}) = P(Z < -2.89)$
= 0.0019

16

Confidence Interval Estimate for the Proportion – Example

Cont'd

For these data,
$$p = \frac{95}{200} = 0.475$$

As
$$n = 200 > 30$$
, $np = 95 > 5$, $n(1-p) = 105 > 5$

 \rightarrow The sampling distribution of p follows Normal distribution approximately

95% confidence interval (C.I.) for π

$$p \pm Z_{\alpha/2} \sqrt{\frac{p(1-p)}{n}} = 0.475 \pm 1.96 \sqrt{\frac{0.475(1-0.475)}{200}}$$
$$= [0.406, 0.544]$$

We are 95% confident that the population proportion of depositors having RMB deposit account is between 0.406 and 0.544

20

Determining Sample Size for the Proportion – Example

$$\pi = \frac{22}{10000} = 0.0022$$

$$n = \frac{\left(Z_{\alpha/2}\right)^2 \pi (1 - \pi)}{E^2} = \frac{(2.575)^2 0.0022(1 - 0.0022)}{0.001^2}$$
$$= 14555.28 \approx 14556$$

Round Up

Test of Hypothesis for the Proportion

Exercise

 H_0 : $\pi = 0.80$ H_1 : $\pi \neq 0.80$

n = 45 > 30np = 39 > 5

n(1-p) = 6 > 5

 $p \sim N$ approximately

At $\alpha = 0.05$

Critical Value = ± 1.96

Reject H_0 if Z < -1.96 or

Cont'd

$$Z = \frac{p - \pi_0}{\sqrt{\pi_0 (1 - \pi_0)}} = \frac{\frac{39}{45} - 0.80}{\sqrt{0.80(1 - 0.80)}}$$

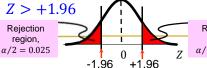

$$\sqrt{n} \qquad \sqrt{4}$$

$$= 1.118$$

= 1.118

At lpha=0.05, do not reject H_0

There is insufficient evidence that the true proportion of customers to be served within 5 minutes upon their arrival is not 80%

Rejection region, $\alpha/2 = 0.025$

29

Confidence Interval Estimate for the Proportion

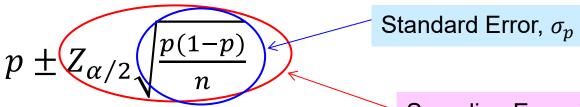

• Since the population proportion, π , is unknown, the standard deviation of p can be estimated by sample standard deviation S_p

$$S_p = \sqrt{\frac{p(1-p)}{n}}$$

- Hence, $Z = \frac{p-\pi}{S_p} \sim N(0,1)$ approximately, for large n
- As the population proportion π is unknown, we may verify the "large enough" condition by np and n(1-p)

Confidence Interval Estimate for the Proportion Cont'd

- Conditions
 - □ The no. of successes, *Y*, follows Binomial distribution
 - Normal approximation can be used
 - $n \ge 30$
 - $np \ge 5$
 - $n(1-p) \ge 5$
- $100(1-\alpha)\%$ Confidence interval estimate

Sampling Error, E

Confidence Interval Estimate for the Proportion – Example

- Among the 200 depositors you randomly selected, 95 of them have RMB deposit account at the bank
- Set up a 95% confidence interval estimate for the population proportion of depositors having RMB deposit account at the bank

Confidence Interval Estimate for the Proportion – Example

For these data,
$$p = \frac{95}{200} = 0.475$$

As $n = 200 > 30$, $np = 95 > 5$, $n(1 - p) = 105 > 5$

95% confidence interval (C.I.) for π

$$p \pm Z_{\alpha/2} \sqrt{\frac{p(1-p)}{n}}$$

We are 95% confident that the population proportion of depositors having RMB deposit account is between 0.406 and 0.544

Cont'd

- Given $\pi =$ population proportion of depositors with multiple accounts = 0.4
- As n = 200 > 30, $n\pi = 80 > 5$, $n(1 \pi) = 120 > 5$ → The sampling distribution of p follows Normal distribution approximately, i.e. $p \sim N(\mu_p, \sigma_p^2)$

$$P(p < 0.3)$$
= $P(Z < \frac{0.3 - 0.4}{\sqrt{\frac{0.4(1 - 0.4)}{200}}}) = P(Z < -2.89)$
= 0.0019

16

Confidence Interval Estimate for the Proportion – Example

Cont'd

For these data,
$$p = \frac{95}{200} = 0.475$$

As
$$n = 200 > 30$$
, $np = 95 > 5$, $n(1-p) = 105 > 5$

 \rightarrow The sampling distribution of p follows Normal distribution approximately

95% confidence interval (C.I.) for π

$$p \pm Z_{\alpha/2} \sqrt{\frac{p(1-p)}{n}} = 0.475 \pm 1.96 \sqrt{\frac{0.475(1-0.475)}{200}}$$
$$= [0.406, 0.544]$$

We are 95% confident that the population proportion of depositors having RMB deposit account is between 0.406 and 0.544

20

Determining Sample Size for the Proportion – Example

$$\pi = \frac{22}{10000} = 0.0022$$

$$n = \frac{\left(Z_{\alpha/2}\right)^2 \pi (1 - \pi)}{E^2} = \frac{(2.575)^2 0.0022(1 - 0.0022)}{0.001^2}$$
$$= 14555.28 \approx 14556$$

Round Up

Test of Hypothesis for the Proportion

Exercise

 H_0 : $\pi = 0.80$ H_1 : $\pi \neq 0.80$

n = 45 > 30

n = 45 > 30np = 39 > 5

n(1-p) = 6 > 5

 $p \sim N$ approximately

At $\alpha = 0.05$

Critical Value = ± 1.96

Reject H_0 if Z < -1.96 or

Cont'd

$$Z = \frac{p - \pi_0}{\sqrt{\pi_0 (1 - \pi_0)}} = \frac{\frac{39}{45} - 0.80}{\sqrt{0.80(1 - 0.80)}}$$

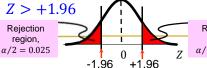

$$\sqrt{n} \qquad \sqrt{4}$$

$$= 1.118$$

= 1.118

At lpha=0.05, do not reject H_0

There is insufficient evidence that the true proportion of customers to be served within 5 minutes upon their arrival is not 80%

Rejection region, $\alpha/2 = 0.025$

29

Confidence Interval Estimate for the Proportion Cont'd

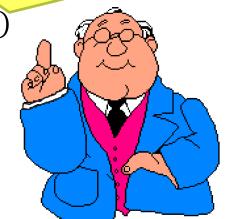

- Special considerations
 - $\ \ \, \text{If } p-Z_{\alpha/2}\sqrt{\frac{p(1-p)}{n}}<0 \text{, we have to replace the lower bound }$ of the confidence interval by 0
 - $lf \ p + Z_{\alpha/2} \sqrt{\frac{p(1-p)}{n}} > 1, \ \text{we have to replace the upper bound}$ of the confidence interval by **1**
- But why?

Factors Affecting Interval Width (Precision)

- Level of confidence, (1α)
 - \square $(1-\alpha) \uparrow \rightarrow |Z$ -value $|\uparrow \rightarrow width of interval <math>\uparrow$
- Sample size, n
 - $n \uparrow \rightarrow \sigma_p \downarrow \rightarrow \text{width of interval} \downarrow$
- Sample proportion, p
 - □ If p increases from 0 to 0.5, then p(1-p) increases from 0 to 0.25, leading to a wider interval
 - □ If p further increases from 0.5 to 1, then p(1-p) drops from 0.25 to 0, leading to a narrower interval

Intervals extend from

$$p - Z_{\alpha/2} \sqrt{\frac{p(1-p)}{n}}$$
 to $p + Z_{\alpha/2} \sqrt{\frac{p(1-p)}{n}}$

Determining Sample Size for the Proportion

Sampling error (or margin of error)

$$E = Z_{\alpha/2} \sqrt{\frac{\pi(1-\pi)}{n}}$$

Solving the equation for n gives

$$n = \frac{(Z_{\alpha/2})^2 \pi (1-\pi)}{E^2}$$

lacksquare If the computed n is not an integer, round it up to nearest integer

Determining Sample Size for the Proportion – Example

- According to the Developments in the Banking Sectors published by Hong Kong Monetary Authority in June 2014, at the end of the first quarter of 2014, 22 credit card lending were found in each 10,000 transactions
- You want to have 99% confidence of estimating the proportion of credit card lending at your bank to within $\pm~0.001$
- What is the minimum sample size being needed?

Determining Sample Size for the Proportion – Example

Cont'd

$$\pi = \frac{22}{10000} = 0.0022$$

$$n = \frac{\left(Z_{\alpha/2}\right)^2 \pi (1 - \pi)}{E^2}$$

Cont'd

- Given $\pi =$ population proportion of depositors with multiple accounts = 0.4
- As n = 200 > 30, $n\pi = 80 > 5$, $n(1 \pi) = 120 > 5$ → The sampling distribution of p follows Normal distribution approximately, i.e. $p \sim N(\mu_p, \sigma_p^2)$

$$P(p < 0.3)$$
= $P(Z < \frac{0.3 - 0.4}{\sqrt{\frac{0.4(1 - 0.4)}{200}}}) = P(Z < -2.89)$
= 0.0019

16

Confidence Interval Estimate for the Proportion – Example

Cont'd

For these data,
$$p = \frac{95}{200} = 0.475$$

As
$$n = 200 > 30$$
, $np = 95 > 5$, $n(1-p) = 105 > 5$

 \rightarrow The sampling distribution of p follows Normal distribution approximately

95% confidence interval (C.I.) for π

$$p \pm Z_{\alpha/2} \sqrt{\frac{p(1-p)}{n}} = 0.475 \pm 1.96 \sqrt{\frac{0.475(1-0.475)}{200}}$$
$$= [0.406, 0.544]$$

We are 95% confident that the population proportion of depositors having RMB deposit account is between 0.406 and 0.544

20

Determining Sample Size for the Proportion – Example

$$\pi = \frac{22}{10000} = 0.0022$$

$$n = \frac{\left(Z_{\alpha/2}\right)^2 \pi (1 - \pi)}{E^2} = \frac{(2.575)^2 0.0022(1 - 0.0022)}{0.001^2}$$

Do Voters Really Vote When They Say They Do?

- On November 8, 1994, a historic election took place in US, in which the Republican Party won control of both houses of Congress for the first time since 1952
- But how many people actually voted?
- On November 28, 1994, Time magazine reported that in a telephone poll of 800 adults taken during the two days following the election, 56% reported that they had voted
- But based on information from the Committee for the Study of the American Electorate, in fact, only 39% of American adults had voted
- Could it be the case that the results of the poll simply reflected a sample that, by chance, voted with greater frequency than the general population?

Do Voters Really Vote When They Say They Do?

Cont'd

- Let's suppose that the truth about the population is that only 39% of American adults voted, i.e. $\pi = 39\% = 0.39$
- We can expect in samples of 800 adults, the size used by the Time magazine poll, the mean is 0.39 and standard error is

0.017, i.e.
$$\mu_p = \pi = 0.39$$
 and $\sigma_p = \sqrt{\frac{\pi(1-\pi)}{n}} = 0.017$

- According to the Empirical Rule, we are almost certain that the sample proportion based on a sample of 800 adults should fall within $3 \times 0.017 = 0.051$ of the truth of 0.39
- In order words, if respondents were telling the truth, the sample proportion should be no higher than 44.1%
 (=39%+5.1%), no where near the reported percentage of 56%

Do Voters Really Vote When They Say They Do?

Cont'd

- We can also find how likely the sample proportion of 0.56 or above to happen
- Given n = 800, $\mu_p = 0.39$ and $\sigma_p = 0.017$
- $P(p \ge 0.56) = P(Z \ge 10) \approx 0$
- It is virtually impossible to have such high proportion of voters voted in the election
- The differences between data may be the result of a variety of factors
 - Differences in the respondents' interpretation of the questions
 - Respondents' inability or unwillingness to provide correct information or recall correct information
