CS1102 Lecture 2 Binary Number System

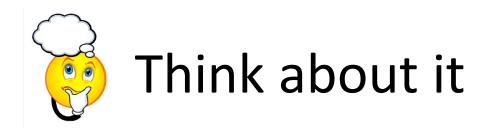

Not to be redistributed to Course Hero or any other public websites

Semester A, 2020-2021

Department of Computer Science

City University of Hong Kong

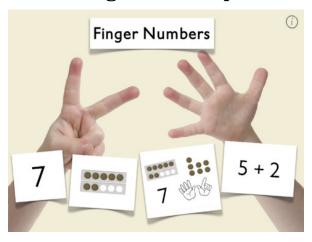

- You may have known or heard people say the followings:
 Computers use binary system to represent information
- But....
 - What is a binary system?
 - How is it different from the number system used by humans?
 - Why and how do computers use binary system?

Number System Used by Humans

• Children often use fingers to help them count

- Humans use these symbols to represent single digits (1-digit number):
 0, 1, 2, 3, 4, 5, 6, 7, 8, 9
- After the largest 1-digit number 9, the next number is represented by a 2-digit number, i.e., 10
 - We say that we count in base 10
 - The number system used by humans is called a decimal system

Binary System

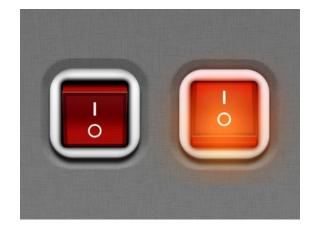

- Under a binary system, we only have 2 symbols: 0, 1
- The above symbols are called bits (binary digit)
 - Who invented "bit"? https://en.wikipedia.org/wiki/Bit
- After the largest 1-bit number 1, the next number is represented by a 2-bit number, i.e., 10
- Numbers in a binary system are in base 2
- Sometimes a number in subscript is used to represent the base, e.g.,
 - $-10_2 = 2_{10}$ [10 in base 2 is equal to 2 in base 10]

Pronounced as "one zero" Pronounced as "ten"

Number System Used by Computers

- Computers use binary system to represent information
- Examples:
 - A light switch may be on (1) or off (0)
 - An electronic circuit may be closed (1) or open (0)
 - A specific location on a tape or disk may have a positive charge (1)
 or negative charge (0)

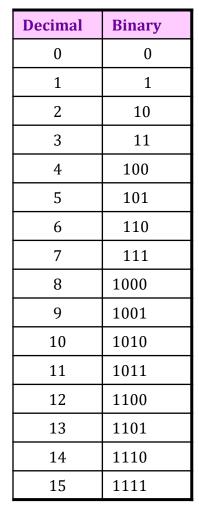

This is the reason why a two-state or binary system is used to represent data and instructions in computer

Conversion between Decimal and Binary System

Given a decimal number, how to convert it to its binary representation (decimal-to-binary conversion)?

Given a binary number, how to convert it to its decimal representation (binary-to-decimal conversion)?

Binary to Decimal Conversion

Let's first try to examine a multiple digit decimal number

- e.g.,
$$375_{10} = 3 \times 100 + 7 \times 10 + 5$$

$$100 + 7 \times 10^{1} + 5 \times 10^{0}$$
hundreds
tens
ones

 This technique can be applied to convert a multiple bit binary number to decimal

- e.g.,
$$1011_2 = 1 \times 2^3 + 0 \times 2^2 + 1 \times 2^1 + 1 \times 2^0$$

= $1 \times 8 + 0 \times 4 + 1 \times 2 + 1 \times 1$
= 11_{10}

Decimal to Binary Conversion

- **Repeated division** can be used to convert a decimal number to binary as follows: Dividend
 - Step 1 divide the value by two and record the remainder
 - Step 2 continue to divide the quotient by two and record the remainder, until the newest quotient becomes zero
 - Step3 the binary representation is the remainders listed from bottom to top in the order they were recorded

Simplified way:

e.g., what is 11_{10} in binary?

Divisor

Quotient

Remainder

$$5 \div 2 = 2 \cdots 1$$
 $2 \div 2 = 1 \cdots 0$
 $1 \div 2 = 0 \cdots 1$

Answer: 1 0 1 1

Answer: 1 0 1

$$\begin{array}{c|c}
2 & 11 \\
2 & 5 & \cdots & 1 \\
2 & 2 & \cdots & 1 \\
\hline
& 1 & \cdots & 0
\end{array}$$

Note on Conversion between Binary and Decimal Numbers

- The techniques from the previous 2 slides are only applicable for positive integers
- Other techniques are used by computer to represent
 - − Negative numbers, e.g., −2 (to be covered later)
 - Fractional numbers, e.g., 3.1415
 - Very large numbers, e.g., 6.022×10^{23}
 - Very small numbers, e.g., 6.626×10^{-34}

Possible Number Range with a Byte

- A byte consists of 8 bits
- The smallest value represented by a byte is: $00000000_2=0_{10}$
- The largest value represented by a byte is: $11111111_2=255_{10}$
- Thus there can be a total of 256 values (0,1,2,.....,254,255) represented by a byte. Alternatively, this range can also be computed as 2⁸

bit 7 bit 6 bit 5 bit 4 bit 3 bit 2 bit 1 bit 0

0/1 0/1 0/1 0/1 0/1 0/1 0/1 0/1

2
$$\times$$
 2 \times 2

Data Size Measurement

- Normally data size is measured by bytes with various order of magnitude:
 - *Kilobytes* (KB): $2^{10} = 1,024$ bytes
 - e.g., a simple text file
 - *Megabytes* (MB): $2^{20} = 1,024 \text{ KB} = 1,048,576 \text{ bytes}$
 - e.g., picture taken by your mobile phone
 - *Gigabytes* (GB): $2^{30} = 1,024 \text{ MB} = 1,073,741,824 \text{ bytes}$
 - e.g., maximum data usage of your mobile plan
 - *Terabytes* (TB): $2^{40} = 1,024 \text{ GB} = 1,099,511,627,776 \text{ bytes}$
 - e.g., storage size of your hard drive
 - *Petabytes* (PB): $2^{50} = 1,024 \text{ TB} = 1,125,899,906,842,624 bytes$
 - e.g., scale of total data size of Netflix movies
 - *Exabytes* (EB): $2^{60} = 1,024 \text{ PB} = 1,152,921,504,606,846,976 bytes$
 - e.g., scale of Dropbox storage system

Hexadecimal System

Under a hexadecimal system, we have the following 16 symbols:

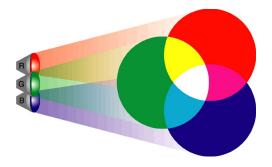

- The above symbols are called nibbles
- After the largest 1-nibble number F, the next number is represented by a 2-nibble number, i.e., 10
- Numbers in a hexadecimal system are in base 16

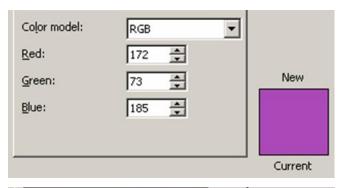

Byte Representing Colors

- Each color shown on screen is a combination of red, green and blue (RGB) with different intensity values
- In a "true color" system, a color is represented by 24 bits, 8 bits for red, 8 bits for green and 8 bits for blue. Each color component, red, green and blue, takes a value ranging from 0 to 255, e.g.,

	Red	Green	Blue	
Purple:	172	73	185	#AC49B9
Yellow:	253	249	88	#FDF958

Note: in HTML, sometimes text or background color is defined in hexadecimal notation.

Conversion between Decimal and Hexadecimal System

Given a decimal number,
how to convert it to its
hexadecimal
representation
(decimal-to-hexadecimal
conversion)?

Decimal	Hexadecimal
0	0
1	1
2	2
3	3
4	4
5	5
6	6
7	7
8	8
9	9
10	A
11	В
12	С
13	D
14	Е
15	F
16	10

Given a hexadecimal number, how to convert it to its decimal representation (hexadecimal-to-decimal conversion)?

Hexadecimal to Decimal Conversion

Remember binary-to-decimal conversion?

- e.g.,
$$1011_2 = 1 \times 2^3 + 0 \times 2^2 + 1 \times 2^1 + 1 \times 2^0$$

= $1 \times 8 + 0 \times 4 + 1 \times 2 + 1 \times 1$
= 11_{10}

• Hexadecimal-to-decimal conversion works in a similar way, while keeping in mind that the input number is in base 16

- e.g.,
$$3C8_{16} = 3 \times 16^{2} + 12 \times 16^{1} + 8 \times 16^{0}$$

$$= 3 \times 256 + 12 \times 16 + 8 \times 1$$

$$= 768 + 192 + 8$$

$$= 968_{10}$$

Decimal to Hexadecimal Conversion

Dividend

- Repeated division can also be used to convert a decimal number to hexadecimal as follows:
 - Step 1 <u>divide the value by 16</u> and record the remainder converted to hexadecimal, i.e., 0,1,2,...,9,A,B,C,D,E,F
 - Step 2 <u>continue to divide</u> the quotient by 16 and record the remainder, <u>until the newest quotient</u> becomes zero
 - Step3 the hexadecimal representation is the remainders listed from bottom to top in the order they were recorded

e.g., what is 968_{10} in hexadecimal?

968
$$\div$$
 16 = 60 \cdots 8

Divisor
Quotient
Remainder

 $3 \div 16 = 0 \cdots 3$

Answer: 3 C 8

Simplified way:

Binary ←→ Hexadecimal Conversion

- So far you have learnt about conversions of
 - Decimal ↔ Binary
 - Decimal ↔ Hexadecimal

How do you convert between binary and hexadecimal numbers?

What if we carry out the following 2 steps for each case?

binary \rightarrow hexadecimal

- 1) binary \rightarrow decimal
- 2) decimal \rightarrow hexadecimal

e.g. 10100101₂ in hexadecimal?

1)
$$10100101_2 = 2^7 + 2^5 + 2^2 + 1 = 165_{10}$$

2)
$$165_{10} = 10 \times 16 + 5 \times 1 = A5_{16}$$

$$\therefore 10100101_2 = A5_{16}$$

hexadecimal \rightarrow binary

- 1) hexadecimal \rightarrow decimal
- 2) decimal \rightarrow binary

e.g. 97₁₆ in binary?

1)
$$97_{16} = 9 \times 16 + 7 \times 1 = 151_{10}$$

$$\therefore 97_{16} = 10010111_2$$

Although you can get the answer by this method, this may not be the most efficient way for calculation!

Binary ↔ Hexadecimal Conversion (2)

Let's look at some examples. Can you identify some patterns?

Hexadecimal	Binary
0	0
1	1
2	10
3	11
4	100
5	101
6	110
7	111
8	1000
9	1001
A	1010
В	1011
С	1100
D	1101
E	1110
F	1111

Hexadecimal	Binary	
<mark>3</mark> 4	11	0100
<mark>3</mark> 9	11	1001
3C	11	1100
3E	11	1110
7 <mark>4</mark>	111	0100
79	111	1001
7 <mark>C</mark>	111	1100
7 <mark>E</mark>	111	1110
C4	1100	0100
C9	1100	1001
CC	1100	1100
C _E	1100	1110
E4	1110	0100
E9	1110	1001
E <mark>C</mark>	1110	1100
EE	1110	1110

hexadecimal → binary:
Each nibble from the hexadecimal
number is converted individually to
a 4-bit binary number
(leading 0s are appended if
required, e.g., from 100 to 0100)

binary → hexadecimal: every 4 bits starting from the right of the binary number are converted individually to a nibble

What is 3A8D₁₆ in binary?

What is 10011011101011₂ in hexadecimal?

Binary Arithmetic

Rules of Binary Addition

$$-0+0=0$$

$$-0+1=1$$

$$-1+0=1$$

- 1 + 1 = 0, and carry 1 to the next more significant bit
- E.g., $00011010 = 26_{10}$ + $00001100 = 12_{10}$ $00100110 = 38_{10}$

Rules of Binary Subtraction

$$-0-0=0$$

0 - 1 = 1, and borrow 1 from the next more significant bit

$$-1-0=1$$

$$-1-1=0$$

- E.g.,

$$00110011 = 51_{10}$$

- $00010110 = 22_{10}$
 $00011101 = 29_{10}$

the concept is the same as how you do carrying/borrowing when adding/subtracting decimal numbers

- Try to add 00095050 + 00005500 in decimal and see how you do the carrying learnt from your primary school
- Try to calculate 00550055-00050550 in decimal and see how you do the borrowing learnt from your primary school

Binary Arithmetic

Rules of Binary Multiplication

$$-0 \times 0 = 0$$

$$-0 \times 1 = 0$$

$$-1 \times 0 = 0$$

$$-1 \times 1 = 1$$

• i.e. add the shifted multiplicand if the bit is 1

Try to calculate 101001 x 110 as decimal numbers by considering the 1st number multiplying with every digit in the 2nd number, appending the right number of 0s on the right (same as shifting) and then adding them

 Binary Division: repeated process of subtraction

Try to calculate 10000111 / 101 in long division form as decimal numbers and remind yourself how you did it in primary school

Word

- A word is the number of bits that can be accessed at one time by the computer central processing unit (CPU). The more bits in a word, the more data a computer can process at one time.
 - E.g., a 64-bit-word computer can access 64 bits (8 bytes) at a time
- Computers represent numbers in binary with a fixed N-bitword
 - Assume that N=4, then 4 bits are used to represent a number, e.g.,

```
0000_2 = 0_{10}

0001_2 = 1_{10}

0010_2 = 2_{10}

.....

1111_2 = 15_{10}
```

 Note that leading 0s (underlined in red in the above examples) are added to make up the 4 bits

Representing Signed Integers in Binary

- So far we have learnt about how to deal with unsigned integers (positive integers or zero) in binary
- How do we represent signed integers that include negative integers, e.g., -2, -11, etc. in binary?
 - You may observe that an integer, whether positive or negative, consists of the sign (+/-) and the magnitude (the quantity without the sign), e.g., +2 (sign = +, magnitude = 2); -2 (sign = -, magnitude = 2)
 - So how about we just use the first bit, i.e., the most significant bit to denote the sign such that we use bit 0 if it is positive or bit 1 if it is negative, and then just represent the magnitude as a positive integer in binary using the remaining bits (same way as before), e.g.,

$$+2_{10} = 0010_{2}$$
 $-2_{10} = 1010_{2}$
 $sign: +$
 $magnitude: 2_{10} = 10_{2}$
 $magnitude: 2_{10} = 10_{2}$
 $magnitude: 2_{10} = 10_{2}$

This is known as the sign-magnitude representation

Problems with Sign-Magnitude Representation

1. What is 0 in binary using sign-magnitude representation?

Assume an 4-bit word size, both of the following cases correspond to 0:

$$+0_{10} = 0000_2$$
 $-0_{10} = 1000_2$

- This is a waste because two different bit patterns are used to denote the same number
- The numbers that can be represented with 4-bit sign-magnitude representation are -7,-6,-5,-4,-3,-2,-1,0,1,2,3,4,5,6,7 (15 numbers)
- 2. How to perform arithmetic?

E.g., what is the result of $0010_2 + 1010_2$?

- If you apply the binary arithmetic from previous slide, you would get 1100_2 as the result, which translates to -4_{10} in sign-magnitude representation.
- However, 0010_2 =+2₁₀ and 1010_2 =-2₁₀, so their sum should be 0 instead.
- You can see that the sign-magnitude representation does not have a trivial way of doing arithmetic with negative numbers

Two's Complement

- Computers use another representation known as the Two's Complement to represent signed integers (positive integers, 0, negative integers)
- Two's Complement
 - Positive integers are represented in the same way as sign-magnitude representation
 - 0 is represented by setting all bits to 0
 - Negative integers are represented by bit patterns obtained by the following steps:
 - 1. Convert the magnitude of the negative number in binary
 - 2. 'Toggle' each bit, i.e., flip all bits $0 \rightarrow 1$ and $1 \rightarrow 0$
 - 3. Add 1 to the binary number to get the resulting representation

Examples with 4-bit word size

$$- +5_{10} = 0101_2$$

$$-0_{10} = 0000_2$$

$$-5_{10} = ?$$

1. Magnitude:
$$+5_{10} = 0101_2$$

3. Add 1:
$$1010_2 + 0001_2 = 1011_2$$

$$\therefore -5_{10} = 1011_2$$

Two's Complement: Negating Numbers

- In fact, as long as you have the two's complement representation of a number x, you can always apply the last 2 steps (toggle and add 1) to obtain the two's complement representation of its negative counterpart, i.e., –x
- Examples with 4-bit word size

$$+5_{10} = 0101_2$$
 $-5_{10} = 1011_2$ Toggle: 0100_2 Add 1: 1011_2 Add 1: 0101_2 $-5_{10} = 1011_2$ $+5_{10} = 0101_2$

Two's Complement: Number Range

Decimal	Two's Complement
+7	0111
+6	0110
+5	0101
+4	0100
+3	0011
+2	0010
+1	0001
0	0000
- 1	1111
-2	1110
-3	1101
-4	1100
- 5	1011
-6	1010
- 7	1001
<u> </u> 8	1 000

- The numbers that can be represented with 4-bit two's complement representation are -8,-7,-6,-5,-4,-3,-2,-1,0,1,2,3,4,5,6,7 (16 numbers)
- You can observe that the most significant (first) bit is still the sign bit such that positive numbers will start with bit 0 and negative numbers start with bit 1
- There is only 1 bit pattern that corresponds to the number 0, with all the bits set to 0

Two's Complement: Arithmetic

- Conventional approach can be used to add binary numbers in two's complement representation
- Examples with 4-bit word size:

As the word size is 4-bit, we only keep the last 4 bits as the result and ignore the extra bit

Two's Complement: Subtraction

- Subtraction can be easily performed by using two's complement and addition
- The expression x y can be calculated as x + (-y), where (-y) is obtained by taking two's complement of y and then added to x
- Examples with 4-bit word size:

Why Two's Complement Works?

• Let's see that 6-6=0:

```
0110<sub>2</sub>-0110<sub>2</sub> = ?

1) Take two's complement of 0110 Toggle: 1001
Add 1: 1010

2) Compute 0110_2+1010_2
0 1 1 0 (+6_{10})
+ 1 0 1 0 (-6_{10})
1 0 0 0 0 (0_{10})
```

• So why 6-6=0? It will be obvious by putting the steps together:

Two's Complement: Overflow

- With 4-bit word size, the possible numbers are -8,-7,-6,-5, -4,-3,-2,-1,0,1,2,3,4,5,6,7
- Problem will arise if you try to add numbers that sum up outside this range
- Examples:

 This problem is known as overflow. You know that there is overflow if you get a negative number after adding 2 positive numbers or if you get a positive number after adding 2 negative numbers

Text Representation

- So far we have learnt about how computers represent numbers, i.e., with a binary system
- How does a computer represent text?
 - The simplest way is to encode each text character with a number
 - For example, if we only need to represent 26 capital letters from A to Z, then we can use a simple encoding scheme A1Z26, i.e., use 1 to represent A, 2 to represent B, ..., 26 to represent Z so 3 19 would mean CS
 - However, A1Z26 can only represent 26 letters and is not enough for computer usage as we need to represent various kinds of characters or symbols
- There are in fact a number of coding schemes and we will introduce a couple of them: ASCII and Unicode

ASCII

 ASCII – American Standard Code for Information Interchange, is the most widely used coding scheme to represent a set of characters (primarily for English), e.g.,

Text: H e l l o !

ASCII (Dec): 72 101 108 108 111 33

ASCII (Hex): 48 65 6C 6C 6F 21

Decimal	Hex	ASCII									
0	0	NUL	32	20		64	40	æ	96	60	`
1	1	SOH	33	21	į.	65	41	Ā	97	61	а
2	2	STX	34	22		66	42	В	98	62	b
3	3	ETX	35	23	#	67	43	С	99	63	С

29	1D	GS	61	3D	=	93	5D		125	7D	}
30	1E	RS	62	3E	>	94	5E	٨	126	7E	~
31	1F	US	63	3F	?	95	5F		127	7F	

ASCII Example

• If we want to know how computer represents the text A1? using ASCII code, then we first look up each of these character from the ASCII code table from previous slide, i.e.

A byte representing the letter A The ASCII code for 'A' is $65_{10} = 41_{16}$ So the computer is using one byte 0 1 1 0 0 with binary value 01000001 to represent it A byte representing the number 1 The ASCII code for '1' is $49_{10} = 31_{16}$ So the computer is using one byte 1 1 0 0 0 0 0 1 with binary value 00110001 to represent it A byte representing the symbol? The ASCII code for '?' is $63_{10} = 3F_{16}$ 0 0 1 So the computer is using one byte with binary value 00111111 to represent it

Most significant bit (MSB)

Least significant bit (LSB)

Unicode

• As it is not sufficient to use ASCII to encode a large set of characters and foreign languages, another coding scheme called Unicode has been proposed. From the website http://www.unicode.org:

The Unicode Standard is a character coding system designed to support the worldwide interchange, processing, and display of the written texts of the diverse languages and technical disciplines of the modern world. In addition, it supports classical and historical texts of many written languages

Lesson Summary

- Computers understand and process information in binary system. Numbers are represented in base-2 where every bit is either 1 or 0.
- A byte has 8 bits and have 256 possible values. It can be used to represent a single character in a computer
- Hexadecimal numbers are in base 16 and in general can represent numbers with fewer nibbles than the number of bits in base 2 or the number of digits in base 10
- Numbers can be converted from one base to another
- Signed integers are represented using two's complement in computers
- Text can be represented in computers by first encoding each character as a number code
