CS1102 Lecture 4 (Part B) Web Development: Javascript

Not to be redistributed to Course Hero or any other public websites

Semester A, 2020-2021
Department of Computer Science
City University of Hong Kong

Javascript

- Javascript is a programming language that can provide instructions for a browser to dynamically generate content for a website or enhance the website interactivity
- Javascript can be embedded in the head section of the webpage,
 with the code defined inside the <script> </script> tags

```
<!DOCTYPE html>
      <html>
        <head>
          <title>JS 1st Example</title>
           <script>
               function myclick() {
                   alert("Welcome to CS1102!");
           </script>
        </head>
        <body>
12
        <!-- Page content begins here -->
13
          <h1>CS1102</h1>
14
          <h2 onclick="myclick();">Click Me</h2>
15
          <!-- Page content ends here -->
16
        </body>
      </html>
```

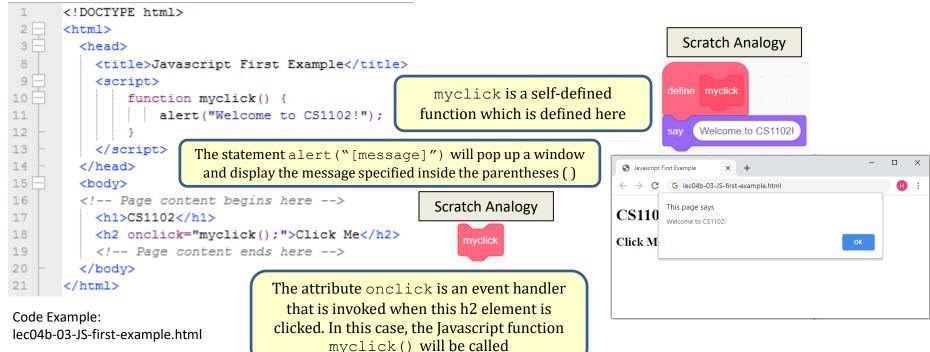

In Scratch, you drag and drop the blocks to form your code.
In Javascript, you have to type the code and you need to be careful to avoid typos which will cause errors in your program.

The semi-colon; is placed at the end of each Javascript statement

Javascript: Website Interactivity

• Website interactivity can be enhanced by detecting a user event and defining the corresponding event handler to perform certain action, e.g., the following program has an event handler that detects if the user clicks on the h2 heading "Click Me" and then calls the function myclick to pop up a message.

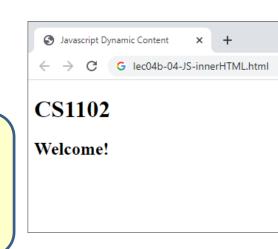

Javascript: Dynamic Content

 The innerHTML property allows the content of an HTML element to be changed dynamically

```
1. Originally the "welcome" div has no content: <div id="welcome"></div>
```

- 2. After the page has finished loading, the onload function is invoked which will call the showDynamicContent() function

```
<! DOCTYPE html>
<html>
  <head>
    <title>Javascript Dynamic Content</title>
    <script>
        function showDynamicContent() {
             document.getElementById("welcome").innerHTML="<h2>Welcome!</h2>";
    </script>
                                                Usually the onload event handler is
  </head>
                                              added as an attribute in the body tag and
  <body onload="showDynamicContent();">
                                               is used to call some Javascript function
  <!-- Page content begins here -->
                                                to carry out some tasks right after the
    <h1>CS1102</h1>
    <div id="welcome"></div>
                                                  webpage has finished loading to
    <!-- Page content ends here -->
                                                      initialize some settings
  </body>
```

</html> Code Example: lec04b-04-JS-innerHTML.html

Comments

- HTML, CSS and Javascript allow programmers to insert comments in the code but their syntax differs
- Comments will be ignored by the browser when the webpage is displayed but it is a
 good practice to insert comments to document what the code logic, such that it will
 be easy for others to understand your code or for you to revisit your code later

```
In Javascript, there are 2 ways to add comments:
      <!DOCTYPE html>
                                    In CSS, comments can be placed between
      <html>
                                                                                          1) Similar to CSS, Javascript comments can be
                                     /* and */ and can span multiple lines
        <head>
                                                                                              placed between / * and * / and can span
          <title>Comments</
                                                                                              multiple lines
               * The following CSS style sets the corresponding div element
                                                                                          2) Javascript comments can also be placed after
11
               with color red */
                                                                                              // until the end of line so this is a single line
12
              #course {
                 color: red;
                                                                                             comment. Note that CSS does not support
                                                                                              this single line comment style
15
          </style>
16 -
          <script>
17
                                 // this function is called after the webpage has been loaded
18
                  /* The following statment dynamically replaces the content
19
                   of the corresponding div elemnt by the given string */
20
                 document.getElementById("course").innerHTML="<h2>Introduction to Computer Studies</h2>";
22
          </script>
                                                                         In HTML, comments can be placed between
23
24
        <body onload="init();">
                                                                         <!-- and --> and can span multiple lines
        <!-- Page content begins here -->
26
          <h1>CS1102</h1>
          <!-- the following div element's content is empty in the HTML
28
               and will be assigned by Javascript after the webpage has been loaded -->
29
          <div id="course"></div>
        <!-- Page content ends here -->
31
        </body>
                             Code Example: lec04b-05-comment.html
      </html>
```

Javascript: Prompting User Input

• Similar to the block ask What's your name? and wait in Scratch, Javascript can use the prompt () function to actively ask the user to input something

In Javascript, variables can be declared by using the syntax var followed by the variable name. There are several rules for defining valid variable names:

- 1. Names are case sensitive, e.g., name and Name are different variables
- 2. Names can begin with letters, underscore , dollar sign \$, but not digits
- 3. Digits can be used in names as long as it is not the first character

22

</body>

4. Names cannot be the same as reserved words such as var, prompt, etc.

Javascript Reserved Words:

https://www.w3schools.com/js/js_reserved.asp

```
<!DOCTYPE html>
      <html>
          <title>Javascript Input Prompt</title>
          <script>
              function init() {
                 var name; // declare a variable
                  name = prompt("What is your name?"); // assign the user input to the variable
                  document.getElementById("hello").innerHTML = "Hello " + name + "!";
14
15
          </script>
                                          "Hello" + name + "!" concatenate
16
        <body onload="init();">
                                           these strings together to from a longer
        <!-- Page content begins here
                                              string. This is similar to the block
          <div id="hello"></div>
                                                                 in Scratch
          Welcome to CS1102!
21
         <!-- Page content ends here
```

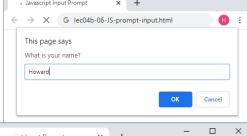

Code Example: lec04b-06-JS-prompt-input.html

Code Example: lec04b-06-JS-prompt-input.html

Hello Howard!

Welcome to CS1102!

The prompt() function is a Javascript built-in function and it pops up a dialog box asking the user to provide input on a textbox. The output of this function is the string input by the user on the textbox

Javascript: Arithmetic Operators

- Javascript arithmetic operators:
 - The 4 operators +, -, *, / are intuitive

 - ++ is the increment operator, x++ will increase the value of the variable x by 1
 - -- is the decrement operator, \times -- will decrease the value of the variable \times by 1

```
<! DOCTYPE html>
                                                                                                                                           ×
     <html>
                                                                            Javascript Arithmetic Operators
         <title>Javascript Arithmetic Operators</title>
9 =
         <script>
                                                                                         G lec04b-07-JS-arithmetic-operators.html
             function init() {
                var s = "";
12
                 var x, y, z;
                                                                       Javascript Arithmetic Operators
14
                      + "x = 7%3 =" + x + "<br /><br />";
16
                      + "Initially y = " + y + "<br />";
                                                                       x = 7\%3 = 1
                                                                                                7%3 is the remainder when 7 is divided by 3
19
                      + "After y++, y = " + y + "<br /><br />";
                                                                                                so it is equal to 1 because 7 = 2 \times 3 + 1
21
                                                                       Initially y = 1
                                                                       After y++, y=2
23
                      + "Initially z = " + z + " < br />";
24
                      + "After z--, z = " + z + " < br /> < br />";
                                                                       Initially z = 2
26
27
                 document.getElementById("display").innerHTML = s;
                                                                       After z - 1 = 1
28
29
         </script>
        </head>
        <body onload="init();">
       <!-- Page content begins here -->
         <h1>Javascript Arithmetic Operators</h1>
         <div id="display"></div>
        <!-- Page content ends here -->
      </html>
                                      Code Example: lec04b-07-JS-arithmetic-operators.html
```

Javascript: Comparison and Logical Operators

- Javascript comparison operators: <, <=, >, >=, ==, !=
 - The first 4 operators <, <=, >, >= are intuitive

Scratch Analogy

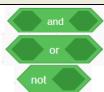

The operator != checks whether the expressions are different (not equal to)

```
<!DOCTYPE html>
      <html>
          <title>Javascript Comparison and Logical Operators</title>
              function init() {
12
                   var input = prompt("Enter a month (1-12):");
13
                   var month = Number(input);
14
                      (month>8 && month <=12)
16
                       s = s+"This month is in Semester A\n";
17
18
                   if (month == 12 || month < 3)
19
                       s = s+"This is a winter month.\n";
20
21
22
                       s = s+"Santa Claus is not coming this month.\n";
23
24
                   alert(s):
25
26
27
28
         <body onload="init();">
         <!-- Page content begins here -->
          <h1>Logical Operators</h1>
          <!-- Page content ends here -->
32
        </body>
```

Javascript logical operators:

- && is the AND operator
- || is the OR operator
- ! is the NOT operator

The expression (month>8 && month <=12) is true if month > 8 AND month <=12, i.e., when month is equal to 9, 10, 11, 12

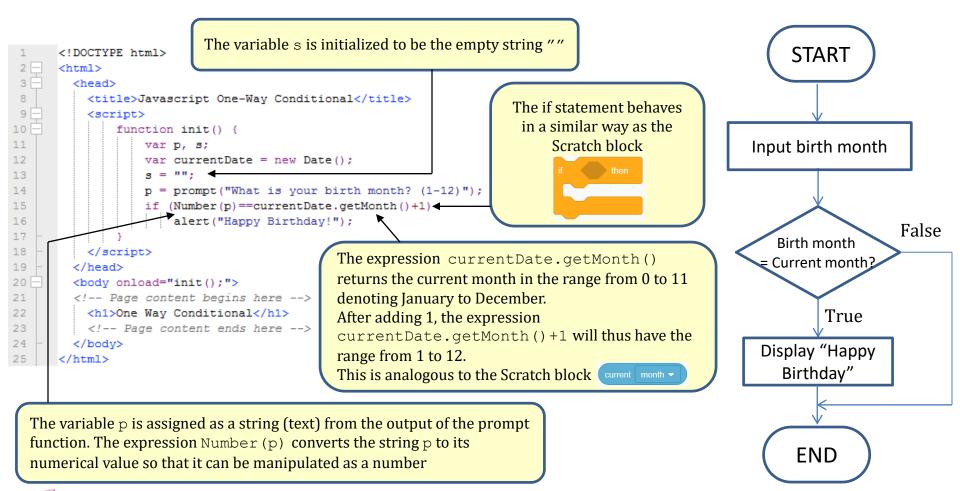

The expression (month== $12 \mid \mid$ month < 3) is true if month is equal to 12 OR month < 3, i.e., when month is equal to 12, 1, 2

The expression (month!=12) is true if month is NOT equal to 12, i.e., when month is equal to 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11

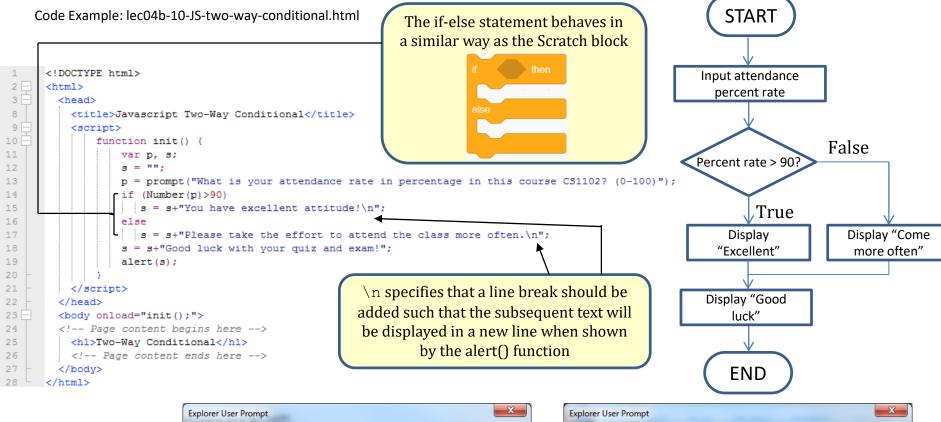

Code Example: lec04b-08-JS-comparison-logical-operators.html

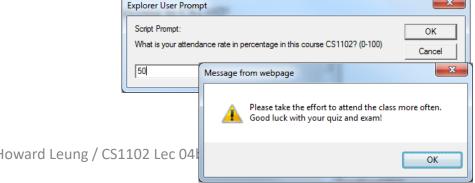

Javascript: One-Way Conditional

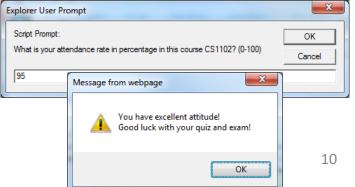

Code Example: lec04b-09-JS-one-way-conditional.html

Javascript: Two-Way Conditional

Javascript: N-Way Conditional

Code Example: lec04b-11-JS-N-way-conditional.html

```
<!DOCTYPE html>
    <html>
       <head>
         <title>Jayascript N-Way Conditional</title>
        <script>
             function init() {
                var p, s, age;
                p = prompt("How old are you? Round to the nearest integer");
                age = Number(p);
                if ( (age >= 0) && (age <= 1) )
                   s = "Infant";
                else if (age <= 4)
                  s = "Toddler";
                else if (age <= 12)
                  s = "Child";
                else if (age <= 19)
                  s = "Teenager";
                else if (age <= 39)
                  s = "Adult";
                 else if (age <= 59)
                  s = "Middle Age Adult";
                  s = "Senior Adult";
                 alert(s);
        </script>
       </head>
      <body onload="init();">
34
        <!-- Page content begins here -->
        <h1>N-Way Conditional</h1>
        <!-- Page content ends here -->
       </body>
```

Age	Boolean Expression	Stage of Life
0-1	age<=1	Infant
2-4	age>=2 AND age<=4	Toddler
5-12	age>=5 AND age<=12	Child
13-19	age>=13 AND age<=19	Teenager
20-39	age>=20 AND age<=39	Adult
40-59	age>=40 AND age<=59	Middle Age Adult
60+	age>=60	Senior Adult

an N-way conditional can be constructed by placing one if-else statement inside another one in a nested manner

The program expects the user to enter a non-negative integer.

- 1. What message do you think the program will output if the user inputs a negative number? Try to trace the program first to anticipate the answer before verifying it by running the program with such kind of input.
- 2. Can you modify this program to output an error message when the input is a negative number?

```
Scratch Analogy
How old are you? Round to the nearest integer. and wait
 sge > 0 or sge = 0 and sge < 1 or sge = 1
  age < 4 or age = 4 1
 Toddler for 2 seconds
     age < 12 or age = 12
  Child for 2 seconds
      age < 19 or age = 19
    Teenager for 2 seconds
      age < 39 or age = 39
     Adult for 2 seconds
        age < 50 or age = 69
       Middle Age Adult for 2 seconds
```

</html>

Javascript: For-Loop

The for-loop is often used to carry out a task for a finite number of times

Code Example: lec04b-12-JS-for-loop.html

```
<!DOCTYPE html>
      <html>
        <head>
          <title>Javascript For-Loop</title>
          <script>
              function init() {
                  var i, N. sum:
                  N = 10:
                  sum = 0:
14
                  for (i=0; i<N; i++) {
                      sum = sum + i:
                  alert ("The sum of the first "+N+" non-negative integer (s) = "+sum);
19
          </script>
20
        </head>
21 -
        <body onload="init();">
        <!-- Page content begins here -->
          Adding the first N integers
          < !-- Page content ends here -->
        </body>
```

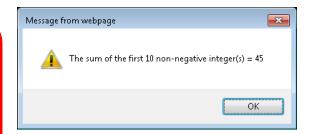

The for-statement, e.g. for (i=0; i< N; i++), contains 3 parts inside the parentheses:

- 1. Initialization: the code is executed at the beginning of the loop e.g., i=0 assigns 0 to the variable i right after the statement sum=0;
- 2. Continuation condition: the tasks specified in the loop are carried out if the continuation condition in the form of Boolean expression is true, otherwise the loop ends if the continuation condition is false e.g., i < 10 is true when i = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 but is false wheni=10:
- 3. Increment statement: this part is executed at the end of each iteration of the loop e.g., i++ means that the variable i is increased by 1 and it is executed at the
 - end of each iteration of the loop after the statement sum = sum + i;
- Note that there should be no semi-colon after the parenthesis,

```
i.e. for (i=0; i< N; i++); is wrong
```

The curly brackets after the for-statement enclose the statements that are executed at each iteration of the for-loop, in this example, sum = sum + i;

You can put multiple statements inside the curly brackets such that all of them will be executed at each iteration of the loop

Javascript: For-Loop (cont.)

```
The code on the left is executed according to the following sequence of operations:
                                         1. N=10
       N = 10:
                                         2. sum=0
                                         3. i=0
                                         4. i<N ⇔ 0<10=true so the loop will continue to run

                                         34.i < N \Leftrightarrow 10 < 10 = false so the loop will end
```

Javascript: While-Loop

The while-loop is used to carry out a task repeatedly as long as a continuation condition is true

Code Example: lec04b-14-JS-while-loop.html

```
<!DOCTYPE html>
      <html>
        <head>
          <title>Javascript While-Loop</title>
          <script>
              function init() {
                  var isInputValid, number:
                  isInputValid = false;
                  while (!isInputValid) {
13
14
                       number = prompt("Input a positive integer");
                       if (isNaN(number)) {
                           alert ("Please enter a NUMBER!");
16
17
18
                       else if (Number(number) <= 0) {
                           alert("Please enter a POSITIVE number!");
20
21
                       else
22
                           isInputValid = true;
23
24
                  alert ("The positive number that you entered is "+number);
25
26
          </script>
27
        </head>
28
        <body onload="init():">
        <!-- Page content begins here -->
          Checking for Positive Number
          <!-- Page content ends here -->
32
        </body>
```

isInputValid is a Boolean variable which has value true or false

- it is set to be false initially
- it will be set to true if the user inputs a positive number

! is the NOT operator and will negate its subsequent **Boolean** expression

isInputValid	!isInputValid
true	false
false	true

isNaN is Javascript built-in function and is used to check whether the given parameter is not a number. It will return true if it is not a number and false if it is a number, e.g.,

```
isNaN(234) \rightarrow false
isNaN("abc") → true
```

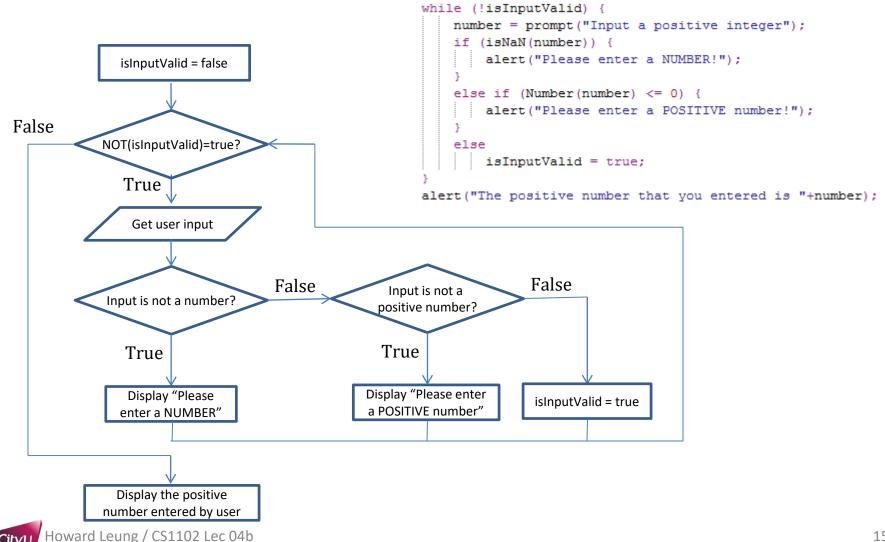

Number is Javascript built-in function and is used to convert the given parameter to a number according to its value such that numeric calculations can be applied, e.g.,

Number ("123")
$$\rightarrow$$
 123
Number ("123") +1 \rightarrow 124
however, "123"+1 \rightarrow "1231"

The curly brackets after the while-statement enclose the statements that are executed at each iteration of the while-loop

Javascript: While-Loop (cont.)

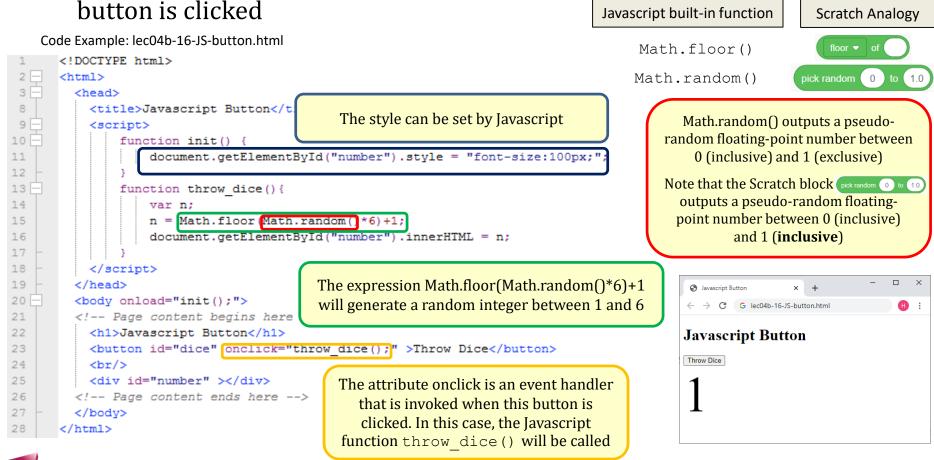

isInputValid = false;

Javascript: Button

A button can be created by using the HTML tag <button>

The attribute onclick can be used to handle the event when the

Javascript: Array

- An array can be used to store a list of elements
- Note that the index of the array starts with 0

```

Interactive Webpage Examples

- Here we provide some specific problems and show you how they can be solved by designing some programs with interactive webpages
- You can try solving the problems yourself before looking at our solution design

Problem 1: List of Numbers and Statistics

• Design a webpage that allows the user to input a list of numbers. The input should be collected one at a time, and validated to make sure that the input is indeed a number. After a valid input is collected, the maximum, minimum, sum and mean among the numbers in the current list should be shown on the webpage.

Building Block 1 for Solving Problem 1: Collecting User Input

- The prompt function was one way to collect input from the user
- Here we introduce another way to collect input from the user by using a textbox
 - 1. In the HTML, the following code can create a textbox:

```
<input type="text" id="textinput" />
```

2. In the HTML, a button can be added to let user click after providing the input in the textbok:

```
<button id="add" onclick="check_and_add();" >Add</putton>
```

3. In the Javascript, the content of the textbox can be extracted and stored in a variable \times by using the following code:

```
var x = document.getElementById("textinput").value;
```

123 Add

- 1) The user enters 123 in the textbox
- 2) The user clicks the "Add" button
- 3) The variable x will be assigned with 123 as a string

Building Block 2 for Solving Problem 1: Storing the List of Numbers

- An array will be used to store the list of numbers input by the user
- Let us use the variable name nlist to denote this array. As the index of a Javascript array starts with 0, we would like to have
 - 1. nlist[0] stores the 1st number input by the user
 - 2. nlist[1] stores the 2nd number input by the user

...

- We need a variable to keep track of how many numbers the user has already input so that we can have the correct index to store each new input. Let us use the variable N for this purpose
 - N should be initialized to 0
 - Each time when a user provides an input, we first check if the input is indeed a number, and if yes, then we do the followings:

```
nlist[N] = Number(x);
N++;
```

- 1) \times is the same variable as defined in previous slide which was assigned the value of the textbox as a string
- 2) The expression Number(x) converts it as a number so that it can be later processed as a number in the calculations
- 3) The variable N should then be incremented by 1

Building Block 3 for Solving Problem 1: Calculating the Statistics (1)

• Calculating the mean is similar to the calculating the sum (by adding each array element) and then dividing by the number of items at the end, i.e.,

```
var sum=0;
for (i=0; i<N; i++)
    sum += nlist[i];
mean = sum/N;</pre>
```

- One common way for finding the maximum value in an array is shown as follows:
 - 1. Initialize a variable called max to be a very small number (say the lower bound if known or the smallest number that can be represented)
 - 2. Compare each element in the array with max. If the element is larger than, then assign max with this element.

In other words, the above variable max holds the value of the maximum element found so far in the array. We need to carefully choose the initial value of max in order for the above algorithm to work. However, since we know that the array contains at list one element by the time we calculate the maximum value, the above algorithm can be modified as follows:

```
var max=nlist[0];
for (i=1; i<N; i++)
    if (nlist[i] > max)
        max = nlist[i];
```

With the above, we initialize max with the first element in the array, and then compare max with each other element and update max if a larger value is found

Building Block 3 for Solving Problem 1: Calculating the Statistics (2)

Finding the minimum value can be achieved in a similar way:

```
var min=nlist[0];
for (i=1; i<N; i++)
    if (nlist[i] < min)
        min = nlist[i];</pre>
```

• Finding the sum, mean, maximum and minimum can be done within the same for-loop shown below:

```
var sum=nlist[0];
var max=nlist[0];
var min=nlist[0];
for (i=1; i<N; i++) {
    sum += nlist[i];
    if (nlist[i] > max)
        max = nlist[i];
    if (nlist[i] < min)
        min = nlist[i];
}
mean = sum/N;</pre>
```

Solution to Problem 1

```

       </script>
       <body onload="clear array();">
                                                          Code Example: lec04b-problem1-number-list-statistics.html
       <!-- Page content begins here -->
        <h1>Problem 1: List of Numbers and Statistics</h1>
        Input a number to be added to your array:
        <input type="text" id="textinput" />
        <button id="add" onclick="check and add();" >Add</button>
                                                                                      Note that one may use the array method push () to add a
        <button id="clear" onclick="clear array();" >Clear Array</putton>
        <br/><br/>
                                                                                        new element to the end of the array and use the array
        Numbers in the array: <br/>
63
         <div id="number_list" ></div>
                                                                                        property length to get the number of elements in the
64
         Some statistics about the numbers in the above array: <br/>
        <div id="statistics" ></div>
                                                                                      array. As other programming languages may not have the
67
      <!-- Page content ends here -->
68
      </body>
```

69 </html>

Add

above method and property defined, this is why we

illustrate a more general way to handle array

Problem 2: Letter Counting

How many F's are there in the following passage?

FINISHED FILES ARE THE RESULT OF YEARS
OF SCIENTIFIC STUDY COMBINED WITH THE
EXPERIENCE OF YEARS

Building Blocks for Solving Problem 2

In the HTML, include the passage inside a div element

```
<div id="passage" >
FINISHED FILES ARE THE RESULT OF YEARS OF SCIENTIFIC STUDY COMBINED
WITH THE EXPERIENCE OF YEARS
</div>
```

 In Javascript, extract the passage from the div element and store it in a variable

```
var s = document.getElementById("passage").innerHTML;
```

 Run a loop to iterate over all characters in the string stored in the above variable and have a counting variable (initialized to 0) increased by 1 if the character is 'F'

s.length returns the length, i.e., the number of characters in the string stored in the variable s

Both count=0 and i=0 are executed as initialization at the beginning of the for-loop

Note that only a single statement count++; needs to be executed when the if-condition is true, so there is no need to use curly brackets {} here

Similarly, in the for-loop, only a single statement if (s[i] == 'F') count++; needs to be executed at each iteration, so there is also no need to use curly brackets {} here

Solution to Problem 2

```
<!DOCTYPE html>
      <html>
        <head>
           <title>Problem 2: Letter Counting</title>
          <script>
11 -
               function init() {
12
                  document.getElementById("passage").style = "font-size:2em;";
14
                                                                             Problem 2: Letter Counting
15 -
               function show answer() {
                                                                             ← → C G lec04b-problem2-letter-counting-v1.html
                  var s = document.getElementBvId("passage").innerHTML;
17
                                                                            Problem 2: Letter Counting (Version 1)
                  for (count=0, i=0; i<s.length; i++)
19
                      if (s[i] == 'F')
                                                                            FINISHED FILES ARE THE RESULT OF YEARS
                         count++;
                                                                            OF SCIENTIFIC STUDY COMBINED WITH THE

24
                                                                            How many 'F' are there in the above text? Answer
25
          </script>
26
        </head>
                                                    Code Example: lec04b-problem2-letter-counting-v1.html
27
        <body onload="init();">
         <!-- Page content begins here -->
          <h1>Problem 2: Letter Counting (Version 1)</h1>
30
          <br/>
31 -
          <div id="passage" >
             FINISHED FILES ARE THE RESULT OF YEARS OF SCIENTIFIC STUDY COMBINED WITH THE EXPERIENCE OF YEARS
          </div>
33
          <br/>
          How many 'F' are there in the above text?
          <button id="answer" onclick="show answer();">Answer</button>
         <!-- Page content ends here -->
37
38
        </body>
      </html>
```

Problem 2: Letter Counting (Extra)

How to add 2 buttons to highlight and unhighlight the F's?

Design:

 Right after the webpage is loaded (use onload event handler), store the passage specified by the div element in a variable text

```
text = document.getElementById("passage").innerHTML;
```

 When the highlight button is clicked, form another variable newtext by replacing all occurrences of 'F' in the variable text by "F"

```
var newtext = text.replace(/F/g, "<span>F</span>");
```

Replace the div element by this variable newtext

```
document.getElementById("passage").innerHTML = newtext;
```

Set the span style to red color

```
span {
    color: red;
}
```

 When the unhighlight button is clicked, replace the div element by the variable text that stores the original passage

```
document.getElementById("passage").innerHTML = text;
```

Solution to Problem 2 (Extra)

Code Example: lec04b-problem2-letter-counting-v2.html

```
<! DOCTYPE html>
    <html>
        <title>Problem 2: Letter Counting</title>
           span
                color: red:
                                The variable text is declared here as a global variable so that all functions
        </style>
        <script>
                                   can have access (e.g., in functions init, highlight, unhighlight)
            var text;
           function init()
                                                                                Note that if you declare the variable text in this function, i.e., if you write
                  = document.getElementById("passage").innerHTML;
                                                                                var text = document.getElementById("passage").innerHTML
           function show answer() {
                                                                             then it will become a local variable and only this function init can have access
              var s = document.getElementById("passage").innerHTML;
                                                                             to it but not others, meaning that the functions highlight and unhighlight
              for (count=0, i=0; i<s.length; i++)
                if (s[i] == 'F')
                                                                                 will not see this assigned value when trying to access the variable text
                 count++;
              alert("There are "+count+" F in the text"):
           function highlight() {
                                                                 The parameter /F/q in the
                                                                                                              Problem 2: Letter Counting
              var newtext = text replace(/F/g, "<span>F</span>");
                                                                 function replace specifies
                                                                                                                 → C G lec04b-problem2-letter-counting-v2.html
              document.getElementById("passage").innerHTML = newtext;
                                                                    that all F's are replaced
40
                                                                                                             Problem 2: Letter Counting (Version 2)
                                                                  globally. If you change this
           function unhighlight() {
                                                                 parameter to "F", then only
              document.getElementById("passage").innerHTML = text
                                                                                                             FINISHED FILES ARE THE RESULT OF YEARS
                                                                the first occurrence (instead
45
46
       </script>
                                                                                                             OF SCIENTIFIC STUDY COMBINED WITH THE
                                                                  of all occurrences) will be
       <body onload="init();">
       <!-- Page content begins here -->
                                                                                                             EXPERIENCE OF YEARS
                                                                             replaced

Lesson Summary

- Javascript is a programming language that can provide instructions for a browser to dynamically generate content for a website or enhance the website interactivity
- You will not be able to learn everything about HTML, CSS and Javascript after only a few lectures, but it serves as a starting point such that you can explore other features on your own
